

On Possible Indicators of Negative Selection in Germinal Centers

Bertrand Ottino-Loffler & Gabriel Victora

Rockefeller University

Feb. 22, 2024

What is a Germinal Center?

GC: Keystone of Adaptive Immunity

Figure: Young (2021)

GC: Small Scale Evolutionary Optimization Alg.

- Body gets hit by pathogen.
- Antigen gets presented to B-Cells in Germinal Center.
- Speedy evolution for **Affinity** (binding ability).
- Get high quality antibodies (yay!)

Figure: Young (2021)

GCs are Neat (For Theory)

- Fast & small scale evolution.
- Constrained system.
- Known objective function.

Question: How *Does* Selection Take Place?

Standard Models: Single Parameter

Traditional population growth model:

$$\text{New cell rate} = (\text{Cell "Fitness"}) * (\text{Number of Cells})$$

Standard Models: Single Parameter

Traditional population growth model:

$$\text{New cell rate} = (\text{birth rate} - \text{death rate}) * (\text{Number of Cells})$$

Normal models: Single Parameter

by Edelstein-Keshet (1988).

1.1 Continuous Growth Models

Single species models are of relevance to laboratory studies in particular but, in the real world, can reflect a telescoping of effects which influence the population dynamics. Let $N(t)$ be the population of the species at time t , then the rate of change

$$\frac{dN}{dt} = \text{births} - \text{deaths} + \text{migration}, \quad (1.1)$$

is a *conservation equation* for the population. The form of the various terms on the right hand side of (1.1) necessitates modelling the situation that we are concerned with. The simplest model has no migration and the birth and death terms are proportional to N . That is

$$\frac{dN}{dt} = bN - dN \quad \Rightarrow \quad N(t) = N_0 e^{(b-d)t}$$

where b , d are positive constants and the initial population $N(0) = N_0$. Thus if $b > d$ the population grows exponentially while if $b < d$ it dies out. This

Figure: Murray (1993)

Birth and Death Are Not The Same

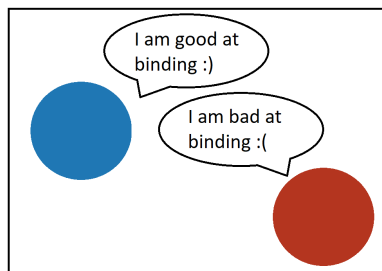

Birth and Death Are Not The Same

Birth Selection/Positive Selection: High fitness = divide faster

Birth and Death Are Not The Same

Death Selection/Negative Selection: High fitness = die slower

Previous Work: The Moran Model

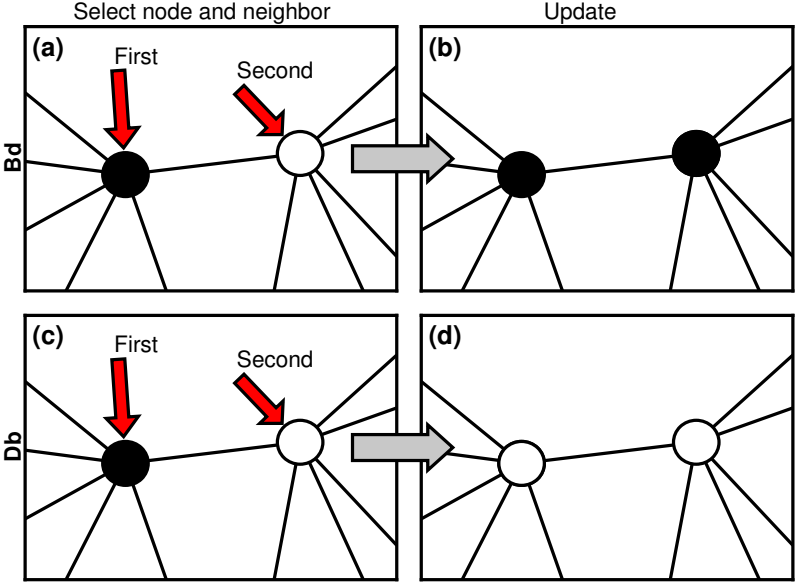

Previous Work: The Moran Model

Definition

The **Moran Model** is a simple model of cancer development.

- Looks at how mutants strains spread through tissues.
- Perserves tissue structure.
- Slooooooow mutation rate.
- Evolves with simple birth-death rules.

Moran Model(s)

Key Metric

Definition

The **Partial Takeover Time** measures how long it takes for a novel mutant to take over $X\%$ of the tissue.

Fixation Times Distinguish Birth and Death

Birth and Death Are Not The Same

Intuition:

- Birth Selection starts fast, slows down near total fixation.
- Death Selection starts slow, but fixates fast.
- Truncation skip slow regime for Birth Selection, changing the qualitative shape.

The Goal

Can we find a convenient signature of Death Selection in Germinal Centers?

Method

We want a model that...

- 1 Recreates the basic dynamics of GCs, and
- 2 Includes as few parts as possible.

We want a model that will produce the strongest possible signal of selection, with a minimum of confounding variables.

Differential Equations

- Equations that model how a set of variables change over time.

Stochastic Processes

- The study of how random events accumulate over time.

Toy-Model Numerics

- Building and running simple simulations to check if our pencil-and-paper calculations make sense.

A Model for Affinity Selection

Only two affinities, High (H) and Low (L) for maximum disparity.

h = fraction of population which is high affinity.

GC has three potential selection mechanisms:

- Birth Selection (r_B),
- Death Selection (r_D),
- Mutational Selection (??).

Typical Selection Curve

$$r_B = 3, r_D = 2, \rho = 0.4$$

Mutational Selection?

- Mutations in GC occur 10^6 times more often than default.
- GCs occasionally have **Clonal Bursts**, where one cell line repeatedly divides.
- When bursting, the line has a **notably lower** mutation rate than normal for the GC.
- This opens the possibility of a **tunable mutation rate**.

Pure Mutational Selection

$$r_B = r_D = 1, \rho_L = 0.6, \rho_H = 0.1$$

Average Selection

Let $\ell = 1 - h$, then the average selection dynamics are given by:

$$\frac{dh}{dt} = \frac{2\rho_L\eta_L}{1 + n/N} \frac{\ell}{r_B h + \ell} + \frac{1 - 2\rho_H\eta_H}{1 + n/N} \frac{r_B h}{r_B h + \ell} - \frac{n/N}{1 + n/N} \frac{h/r_D}{h/r_D + \ell}$$

Skew Hypothesis

Skew Hypothesis

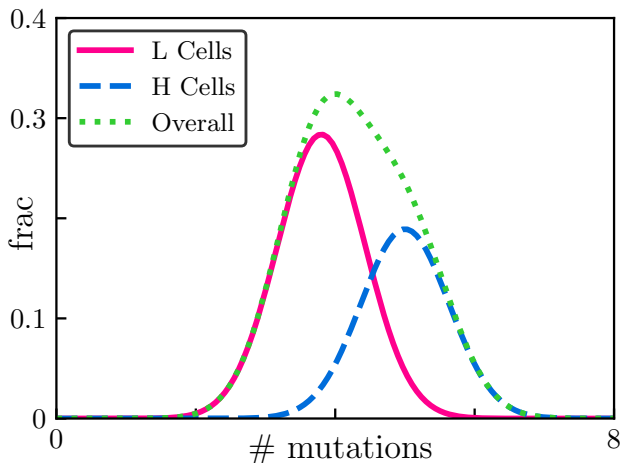

Figure: Tatsuya (2022)

Skew Hypothesis

Since L and H have different levels of mutational activity, would they separate?

Skew Hypothesis: Pilot Data

$r_B = 3.0, r_D = 2.0$

$r_B = 3.0, r_D = 2.0$

How is Skew Measured?

How is Skew Measured?

Definition

The k th **Moment** of N numbers is:

$$\langle x^k \rangle = \frac{x_1^k + x_2^k + \dots + x_N^k}{N}$$

How is Skew Measured?

Definition

The shape of a distribution with mean μ is determined by its **Central Moments**:

$$C(x^k) = \frac{(x_1 - \mu)^k + (x_2 - \mu)^k + \dots + (x_N - \mu)^k}{N}$$

- The second central moment measures the width of the distribution (the **Variance**).

How is Skew Measured?

Definition

The **Skew** of a distribution is given by:

$$\text{Skew}(x) = \frac{C(x^3)}{C(x^2)^{3/2}}$$

Calculation Outline: Mutation Dynamics

$$h_m = \frac{\text{number of H cells with } m \text{ mutations}}{\text{number of cells}}$$

$$l_m = \frac{\text{number of L cells with } m \text{ mutations}}{\text{number of cells}}$$

$$\begin{aligned}\langle m^k \rangle &= k\text{'th moment of mutation distribution} \\ &= \sum_m (h_m + l_m) m^k\end{aligned}$$

Calculation Outline: Linear Structure

$$\partial_t \langle m_H^k \rangle = A_H \langle m_H^k \rangle + B_H \sum_{w=0}^k \binom{k}{w} \langle m_H^k \rangle + C_H \sum_{w=0}^k \binom{k}{w} \langle m_L^k \rangle$$

$$\partial_t \langle m_L^k \rangle = A_L \langle m_L^k \rangle + B_L \sum_{w=0}^k \binom{k}{w} \langle m_H^k \rangle + C_L \sum_{w=0}^k \binom{k}{w} \langle m_L^k \rangle$$

Calculation Outline: Back of Envelope

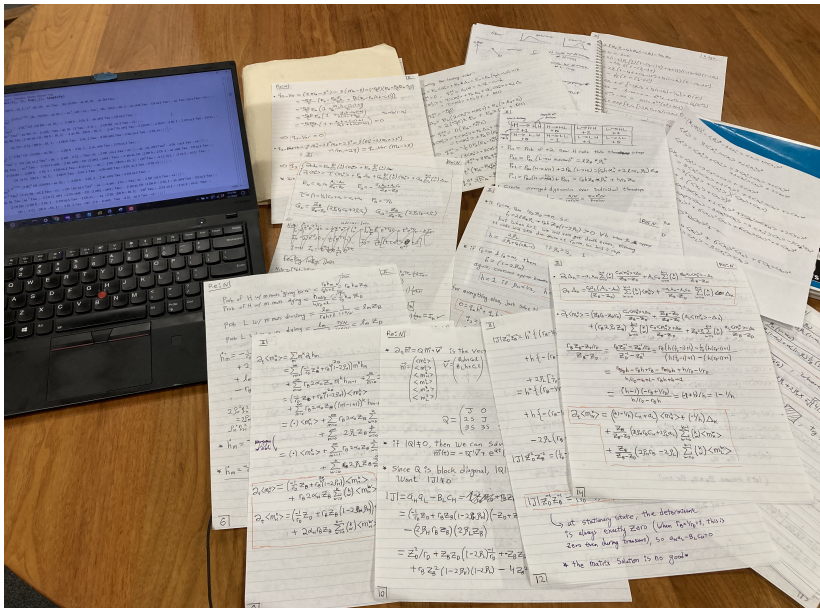

$$\text{Skew} = \frac{C(m^3)}{C(m^2)^{3/2}}$$

$$C(m^3) \approx \langle m^3 \rangle = \mathbb{O}(t^3)$$

$$C(m^2) \approx \langle m^2 \rangle = \mathbb{O}(t^2)$$

Therefore Skew \rightarrow Constant

NOPE

Recall

$$- \dot{q}_m = (m_1 - m_2) \dot{q} - (m_1 + m_2) \dot{q}_2$$

$$= -m_2 \dot{q} + m_2 \dot{q}_2 - m_1 \dot{q} - m_1 \dot{q}_2$$

$$= -m_1 \dot{q} + m_2 \dot{q}_2 - m_1 \dot{q} - m_1 \dot{q}_2$$

$$= -2m_1 \dot{q} + (m_2 - m_1) \dot{q}_2$$

$$\Rightarrow \dot{q}_m = 2\dot{q} - \frac{m_2 - m_1}{m_1 + m_2} \dot{q}_2$$

... (more equations) ...

... (more notes) ...

\dot{q}_1	\dot{q}_2	\dot{q}_3
\dot{q}_1	\dot{q}_2	\dot{q}_3

... (more notes) ...

Recall

Rate of H of system "long time" $\langle \dot{q}_m \rangle = \frac{d}{dt} \langle q_m \rangle$

Rate of H of system "short" $\langle \dot{q}_m \rangle = \frac{d}{dt} \langle q_m \rangle$

... (more notes) ...

... (more notes) ...

... (more notes) ...

... (more notes) ...

... (more notes) ...

Calculation Outline: Using Careful Methods

$$\text{Skew} = \frac{C(m^3)}{C(m^2)^{3/2}}$$

where

$$C(m^3) = \langle m^3 \rangle - 3\langle m^2 \rangle \langle m \rangle + 2\langle m \rangle^3 = \mathbb{O}(t)$$

$$C(m^2) = \langle m^2 \rangle - 2\langle m \rangle^2 = \mathbb{O}(t)$$

Mutations: The Truth

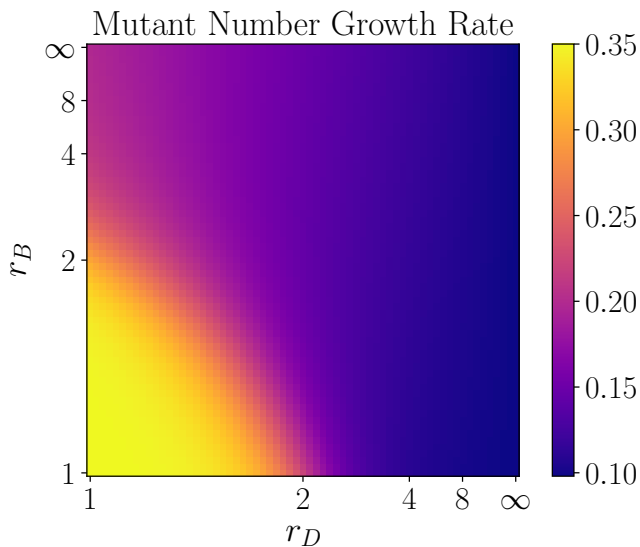

Mutations: The Truth

$$\text{Skew} = \mathcal{O}(t^{-1/2}) \rightarrow 0$$

Dynamical Footprint of Selection

Dynamical Footprint of Selection

Ancestry Hypothesis

Ancestry Hypothesis

Figure: Tatsuya (2022)

Ancestry Hypothesis

$$F_H = \frac{\text{number of H cells with H ancestors}}{\text{number of H cells}}$$

$$F_L = \frac{\text{number of L cells with H ancestors}}{\text{number of L cells}}$$

Ancestry Hypothesis: False

Notably, F_H and F_L **only** depend on the combined $r_B r_D$.

Ancestry Hypothesis: Alternates

Is there anything static that distinguishes r_D and r_B ?

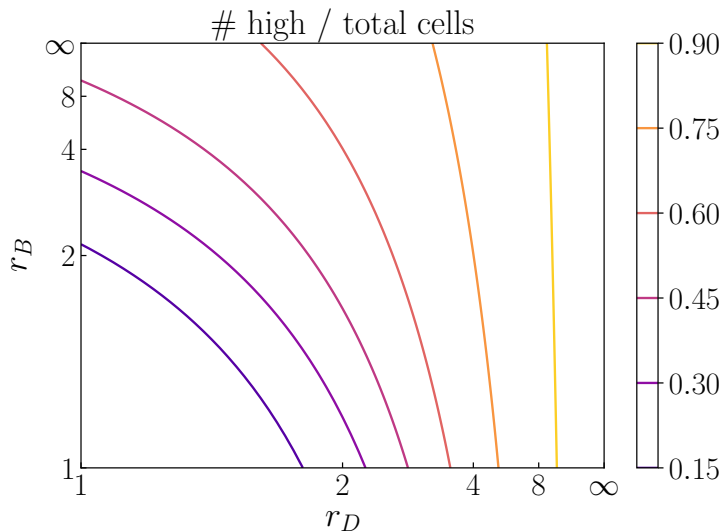

Overall selectivity

$$\text{Fraction of cells which are High affinity} = \frac{1}{1 + r_B g(r_B r_D)}$$

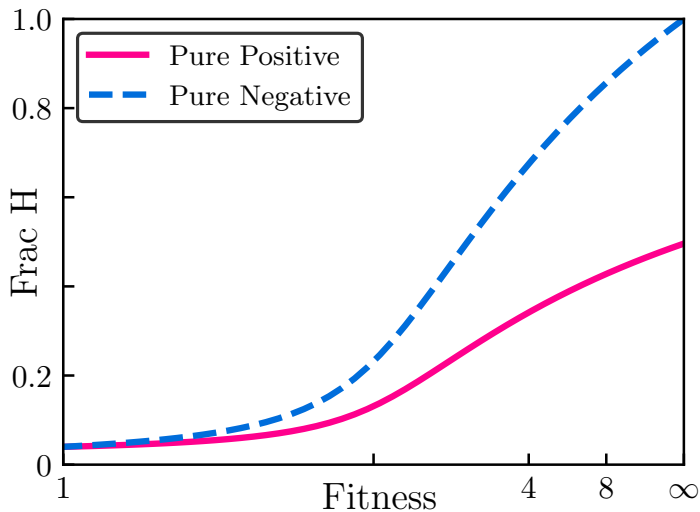

Overall selectivity

Overall selectivity

Overall selectivity

Static Signals of Selection Scheme?

Criteria	Status
Mutation Distribution Shape	Nope
Mutation Dynamics	Sure
Preferential Ancestry	Not Really
Overall Selection Strength	Yep

Combine from multiple sources:

If we combine two metrics, we can solve for fitness, e.g.

$$r_B = \left(\frac{L \rightarrow H \text{ mutation rate}}{H \rightarrow H \text{ mutation rate}} \right) \left(\frac{F_H}{1 - F_H} \right) \left(\frac{1 - h}{h} \right)$$

... but we want qualitative indicators, not just quantitative ones.

Thanks to Tatsuya Araki, Kevin O'Keffee, Daniel Abrams, Juhee Pae, & Arup Chakraborty for the comments.
